

Orbits

The first artificial satellite sputnik

Rocket Launch

Consider a rocket launched from the surface of the earth with velocity v_0 , if its height above the ground is x then

$$\frac{dv}{dt} = \frac{-GM_E}{(R_E+x)^2}$$

$$\frac{dx}{dt} = v \frac{dv}{dx} = v \frac{-GM_E}{(R_E+x)^2}$$

$$\int_{v_0}^v v \, dv = \int_0^x \frac{-GM_E}{(R_E+x)^2} \, dx$$

$$\frac{1}{2}(v^2 - v_0^2) = \frac{GM_E}{R_E+x} - \frac{GM_E}{R_E}$$

$$v^2 = v_0^2 + 2\left(\frac{GM_E}{R_E+x} - \frac{GM_E}{R_E}\right)$$

We can see whether or not the rocket achieves escape velocity by considering the limit as $x \rightarrow \infty$

Escape Velocity

$$v^2 = v_0^2 + 2\left(\frac{GM_E}{R_E+x} - \frac{GM_E}{R_E}\right)$$

as $x \rightarrow \infty$ the object will escape if

$$0 \geq v_0^2 - \frac{2GM_E}{R_E}$$

For the object to escape

$$v_0 \geq \sqrt{\frac{2GM_E}{R_E}}$$

$$M_E = 5.98 \times 10^{24} \text{ kg}$$

$$R_E = 6380 \text{ km}$$

$$G = 6.67 \times 10^{-11} \text{ Nm}^2 \text{ kg}^{-2}$$

$$\rightarrow v_0 = 11,200 \text{ ms}^{-1}$$

Satellites

For a circular orbit a satellite of mass m must have a velocity such that the gravitational acceleration is the same as the centripetal acceleration.

$$G \frac{m M_E}{r^2} = \frac{mv^2}{r}$$

$$v_{\text{circular}} = \sqrt{\frac{GM_E}{r}}$$

In the video below, from Professor Mike Zingale's courses [here](#) you see the orbits of two planets around a star, neglecting the gravitational force between the planets themselves. This is useful for demonstrating Kepler's third law. We work in units of AU, years, and solar masses. The semi-major axes are picked such that one planet has an orbital period of 1 year and the other of 2 years.

As the animation plays, you should see that the speed of the outer planet varies, becoming fastest at perihelion and slowest at aphelion. You will also see that the outer planet takes longer to complete its orbit around the Sun, since P2 ~ a3.

Geosynchronous satellite

For a satellite to have a fixed position above the Earth's surface it must have the same **angular** velocity as a point on the Earth's surface. Another way of looking at this is that the satellite must take exactly one day to complete it's path.

$$\frac{2\pi r}{v} = 1 \text{ day} = 86,400 \text{ s}$$

Using the equation for the velocity $v = \sqrt{\frac{GM_E}{r}}$

$$2\pi \frac{r^{3/2}}{\sqrt{GM_E}} = 86,400 \text{ s}$$

$$r = (86,400 \frac{\sqrt{GM_E}}{2\pi})^{2/3} = 4.23 \times 10^7 \text{ m} = 42,300 \text{ km}$$

(36,000 km above surface)

Mass of Earth $M_E = 5.9742 \times 10^{24} \text{ kg}$

Gravitational Constant $G = 6.67 \times 10^{-11} \text{ Nm}^2 \text{ kg}^{-2}$

GPS

GPS satellites are essentially extremely accurate clocks that continually broadcast their position and the time, which an Earth based receiver can use to calculate it's own position, so long as it can receive at least 4 signals. It is not desirable for GPS satellites to be in geostationary orbits.

A GPS satellite orbits about 20,200 km above the surface of the Earth (or at a radius of 26,600 km from the center of the Earth.)

How many times a day do the GPS Satellites go round the Earth?

$$v = \sqrt{\frac{GM_E}{r}}$$

Mass of Earth $M_E = 5.9742 \times 10^{24} \text{ kg}$

Gravitational Constant $G = 6.67 \times 10^{-11} \text{ Nm}^2 \text{ kg}^{-2}$

GPS problem solution

Number of seconds for a GPS satellite to go round the Earth $\frac{2\pi r}{v} = 2\pi \frac{r^{3/2}}{\sqrt{GM_E}} = 2\pi \frac{(2.66 \times 10^7)^{3/2}}{\sqrt{6.67 \times 10^{-11} \times 5.9742 \times 10^{24}}} = 43,200$

Times round the earth in a day = Seconds in one day/Number of seconds for a satellite to go round the Earth

Seconds in one day = $24 \times 60 \times 60 = 86400$

Times round the earth in one day ≈ 2

$$v = 3870 \text{ m/s}$$

This is fast enough that the clock on a GPS satellite is slightly slower than one on Earth because of **special relativity**. However due to **general relativity** the difference in the gravitational force between the surface of the Earth and the height of the satellite causes the clock to go faster than one on Earth. These two effects need to be taken in to account for the GPS system to work.

Elliptical Orbits

Recall from the last lecture that the escape velocity is

$$v_E = \sqrt{\frac{2GM_E}{R_E}}$$

Compare this to

$$v = \sqrt{\frac{GM_E}{r}}$$

and $r \gg R_E$

So there are velocities above the velocity required for a circular velocity, but less than escape velocity. These lead to elliptical orbits.

Elliptical Orbit:

So there are velocities above the velocity required for a circular velocity, but less than escape velocity. These lead to elliptical orbits.

A simple animation showing how the orbit of a projectile around Earth changes as we increase the change the tangential velocity from less than the circular velocity to greater than the escape velocity. (This script uses the image earth.png; image credit: NASA/Apollo 17)

Kepler's Laws

The elliptical orbits of the planets can be described by **Kepler's Laws**. These were advanced nearly a century before Newton's Law of Gravitation by **Johannes Kepler**.

1. The orbit of every planet is an ellipse with the Sun at a focus.
2. The line joining a planet and the Sun sweeps out equal areas during equal intervals of time.
3. The square of the orbital period of a planet is directly proportional to the cube of the semi-major axis of it's orbit

Kepler's First Law

The orbit of every planet is an ellipse with the Sun at a focus.

Kepler's Third Law

The square of the orbital period of a planet is directly proportional to the cube of the semi-major axis of it's orbit.

So if two planets have semimajor axes s_1 and s_2 then their periods can be related to each other via the relation

$$(\frac{T_1}{T_2})^2 = (\frac{s_1}{s_2})^3$$

It follows that s^3 should be the same for each planet.

The eccentricity is the deviation of the orbit from circular, Earth's eccentricity is 0.017, which is not very much.

Eccentricity

The following video shows how varying the eccentricity of an ellipse changes the shape.

Credit: Prof. Zingale

In [6]:

```
from IPython.display import HTML
HTML("""
<div align="middle">
<video width="80%" controls>
<source src="Videos/eccentricity.mp4" type="video/mp4">
</video></div>""")
```

Out[6]:

Orbits of Planets

The orbits of most of the planets have low eccentricity. Pluto is more eccentric than the others...but it is also no longer a planet,

mainly because we have found many more objects out there which are better described as **dwarf planets**. Sedna is the most distant known object in the solar system and is about two-thirds the size of Pluto..and as you can see has a very long and eccentric orbit.

Kepler's Second Law

The line joining a planet and the Sun sweeps out equal areas during equal intervals of time.

Credit: Prof. Zingale

In [7]:

```
from IPython.display import HTML
HTML("""
<div align="middle">
<video width="80%" controls>
<source src="Videos/second_law.mp4" type="video/mp4">
</video></div>""")
```

Out[7]:

Derivation of Kepler's Third Law

We will derive Kepler's Third Law for the special case of a circular orbit.

We consider only the force between the sun and the planet (ie. we ignore the force from the other planets.)

$$G \frac{m_s M_s}{r_p^2} = m_p \frac{v_p^2}{r_p}$$

$$v_p = \frac{2\pi r_p}{T_p}$$

$$G \frac{m_s M_s}{r_p^2} = m_p \frac{4\pi^2 r_p}{T_p^2}$$

$$T_p^2 = \frac{4\pi^2 r_p^3}{GM_s}$$

So for a circular orbit we have shown that the square of the orbital period of a planet is directly proportional to the cube of the semi-major axis of it's orbit (r_p for a circle).
